

Controlling Platform-Change Directive

Purpose of this revision

This revision changes **one thing only: the implementation platform**.

It does **not** change the project, product, end goal, scope, workforce, workflows, operating model, MCP requirement, dashboard requirement, LLM requirement, guardrails, storage requirements, automation requirements, domain-hosting requirement, or completion standard.

The previous Cloudflare implementation is no longer the platform being continued.

The system is to be built **from scratch on the replacement platform** while preserving the existing end-goal specification.

This is a platform replacement, **not a product redesign**.

What changed

The previous handoff contained implementation language tied specifically to Cloudflare, including references to Cloudflare Workers, Durable Objects, D1, R2, Wrangler, Cloudflare Access, Cloudflare service bindings, Cloudflare-specific deployment, and reconciliation of existing live Cloudflare resources.

Those platform-specific implementation requirements are no longer controlling.

Do not continue, repair, reconcile, complete, migrate, or preserve the former Cloudflare deployment merely because it appears in previous project material.

Do not treat the existing Cloudflare implementation as the foundation of the new build.

Do not interpret prior Cloudflare resources as required components of the finished system.

The replacement platform must implement the **same required system and end goal**.

What did NOT change

The following requirements remain controlling and are not open for reinterpretation as part of the platform change.

1. This remains an MCP system

The completed system includes MCP as part of the required operating environment.

MCP is not being removed because Cloudflare is being removed.

The system must provide the MCP functionality required for Dayna, approved AI workers, approved AI clients, tools, context, files, tasks, agents, and system functions to interact through the completed environment.

Any old wording that equated MCP with a particular Cloudflare Worker implementation must be changed only enough to remove the Cloudflare dependency.

The MCP requirement itself remains.

2. This remains a live server-based system

This is not a collection of prompts, local files, disconnected scripts, static mockups, or isolated agent definitions.

It is a functioning live system.

The required server-side environment remains part of the build.

Removing Cloudflare does not remove the server requirement.

The replacement platform must provide the infrastructure necessary for the live system to operate.

3. This remains a live HTML dashboard for Dayna and the AI workers

The dashboard remains part of the end goal.

It is not merely an administrative interface for developers.

It is part of the working environment through which Dayna and the AI workforce interact with the system.

The finished dashboard must be connected to actual system state.

It must not be a disconnected prototype, static simulation, sample interface, or browser-only representation of work occurring somewhere else.

The live dashboard must expose the appropriate real system information, including as applicable:

- incoming work;
- current work;
- agent ownership;
- routing;
- task status;
- files;
- photos;
- storage workflows;
- review queues;
- agent outputs;
- evidence;
- uncertainty;
- corrections;
- approvals;
- failures;
- completed work;
- follow-ups;
- living context;
- system status.

Removing Cloudflare changes where and how this is implemented.

It does not remove or reduce the dashboard.

4. This remains an LLM-based system

The completed ecosystem includes an operational LLM layer.

The LLM is not merely an external chatbot used during development.

It is part of the functioning system used by the permanent AI workforce.

The permanent agents must be capable of using the appropriate LLM capability as part of their actual work.

The previous platform change does not remove this requirement.

5. The LLM and agents remain governed by guardrails

The completed system must retain the defined occupational, permission, evidence, provenance, uncertainty, review, approval, handoff, privacy, and failure boundaries.

Removing the previous platform does not remove the guardrails.

Guardrails are part of the behavior of the system and workforce, not a feature belonging to Cloudflare.

The system must continue to enforce the distinctions defined in the permanent occupational workforce blueprint, including:

- what each agent may do;
- what each agent may not do;
- what each agent may read;
- what each agent may write;
- what requires evidence;
- what requires approval;
- what requires another occupational role;
- what must be retained as uncertain;
- what must be preserved as an original;

- what must be recorded;
 - what must be handed off;
 - what constitutes failure;
 - what constitutes completion.
-

6. The permanent 40-role occupational workforce remains unchanged

The supplied:

A) Permanent Occupational Workforce Blueprint

remains controlling.

The 40 roles are not being reconsidered because the platform changed.

Do not:

- collapse the roles;
- merge roles;
- remove roles;
- create a replacement workforce;
- substitute generic agents;
- replace the roles with framework-generated agent types;
- reinterpret the roles to fit the replacement platform;
- reduce their responsibilities;
- expand their authority;
- change their occupational boundaries.

Provider-specific terms embedded inside a role definition may be replaced with implementation-neutral equivalents only when necessary to remove the obsolete Cloudflare dependency.

The occupational meaning of the role must remain unchanged.

7. The boundary and overlap matrix remains unchanged

The supplied:

B) Boundary and Overlap Matrix

continues to govern handoffs and occupational separation.

A platform change does not change who owns a function.

The software implementation must accommodate the workforce boundaries rather than rewriting the workforce to accommodate the software.

8. The build remains larger than the permanent workforce

The 40 permanent occupational agents are one major component of the finished ecosystem.

They are not the entire build.

The broader build still includes the technical environment required for those agents and Dayna to work together.

This includes the MCP system, server environment, live HTML dashboard, LLM layer, guardrails, storage, file handling, photo/media handling, workflows, automation, context, permissions, routing, evidence, records, review, recovery, and other system functions already specified by the project.

Do not reduce the project to creating 40 agents.

Do not substitute a roster, registry, prompt library, skill library, or agent directory for the complete system.

9. Storage containers remain a required system function

The completed system must provide the storage environment required by the project.

The term **container** in the project requirements refers to the functional storage and organizational spaces needed by the workflows.

Cloudflare R2 is no longer prescribed.

The requirement for storage containers remains.

The system still requires appropriate storage locations for material such as:

- original documents;
- original photos;
- original media;
- working copies;
- derivatives;
- classified material;
- grouped material;
- agent-ready material;
- review material;
- completed outputs;
- catalogued records;
- archived material;
- provenance-preserved material;
- other workflow-specific storage defined by the system.

The receiving software agent determines how those requirements are implemented on the replacement platform.

It does not determine whether those requirements continue to exist.

10. File intake and automatic workflows remain required

Dayna must be able to place material into the system and have the appropriate automated workflow begin.

The system is not intended to require Dayna to manually organize every file, select every agent, identify every workflow, rename every object, or move every item through every processing stage.

Files entering the system must be capable of triggering the required automated processing.

The exact workflow depends on the material and the qualified occupational functions required.

This requirement remains unchanged.

11. Photo storage and automatic photo processing remain required

The system must provide real photo/media storage and processing workflows.

The photo workflow remains capable of handling functions already established by the project, including:

- accepting photo batches;
- preserving originals;
- analyzing images;
- grouping related images;
- detecting duplicates;
- identifying poor or unusable images;
- determining relevant workflow;
- extracting useful information;
- classifying material where appropriate;
- creating meaningful working filenames;
- renaming appropriate working files or derivatives;
- placing material into the appropriate storage containers;
- connecting media to the relevant item, project, client, business, workflow, or record;
- preparing working derivatives;
- supporting resale-photo preparation;
- routing work to the appropriate qualified occupational agents;
- triggering subsequent workflow stages;
- escalating uncertainty rather than inventing information.

The storage platform may change.

The photo workflow does not disappear.

12. Original preservation remains required

Original files and original photos must remain distinguishable from processed material.

Analysis, renaming, organization, editing, extraction, conversion, classification, or derivative generation must not destroy the relationship to the original source.

The system must retain provenance between originals and subsequent working material.

Changing platforms does not change this requirement.

13. Automatic routing remains required

The system must determine which qualified occupational functions are required for accepted work and route that work appropriately.

Dayna is not expected to manually select the correct agent for every step.

Where work crosses occupational boundaries, the system must support the required handoff.

Removing the previous platform does not turn the system into a manually operated collection of agents.

14. Living context and continuity remain required

The completed system must preserve the living work context necessary for Dayna and the AI workers to continue work over time.

The system must retain the required distinctions among:

- Dayna's own statements;
- agent interpretations;
- evidence;
- corrections;
- decisions;
- active state;
- uncertainty;
- provenance;

- permissions;
- superseded information;
- unfinished work.

Changing the hosting platform does not remove the continuity requirement.

Dayna must still be able to leave and return without manually rebuilding the agents' understanding of ongoing work.

15. Corrections remain part of the operating system

Dayna must be able to correct the system when:

- something is misidentified;
- something is routed incorrectly;
- an assumption is wrong;
- a fact has changed;
- an agent misunderstood an instruction;
- a file or photo belongs somewhere else;
- context is outdated;
- an output is incorrect.

Corrections must be capable of affecting the appropriate authorized downstream system state.

Changing platforms does not change this requirement.

16. Review and approval workflows remain required

Where the existing occupational definitions require review or approval, those controls remain.

The replacement platform must support those workflows.

The software implementation must not convert an approval-required action into an autonomous action merely because the replacement technology makes automation possible.

17. Failure and recovery remain required

The completed system must represent failures as failures.

Agents and workflows must not silently fabricate successful completion when an operation failed.

Interrupted work must be recoverable where required.

System state must make it possible to determine:

- what was attempted;
- what completed;
- what failed;
- what remains pending;
- what requires review;
- what can resume.

The underlying platform may change.

The recovery requirement remains.

18. The existing business domain remains part of the end goal

The completed live system is intended to operate from Dayna's existing/old business domain as already specified by the project.

Removing Cloudflare does not remove the domain-hosting requirement.

The replacement platform must ultimately support the required live system under that domain.

Do not reinterpret the platform change as permission to replace the domain requirement with a unrelated vendor URL, localhost-only system, temporary development address, or separate product identity as the finished state.

Temporary development environments may exist during implementation.

They are not the end state.

19. This remains intended for a new, low-cost business environment

The system must be appropriate to the economic reality of a new business.

The requirement to control unnecessary cost remains.

This does not authorize reduction of the defined end goal.

It means the implementation should avoid unnecessary platform expense, duplicate services, or needless recurring infrastructure where the same required functionality can be provided appropriately at lower cost.

Cost considerations influence implementation choices.

They do not redefine the product.

Previous implementation material

Previous Cloudflare-related code, repositories, configurations, dashboards, Workers, databases, storage definitions, MCP work, tests, prompts, skills, registries, architectural experiments, and other implementation material are historical/reference material.

They may be examined when useful.

They are not the controlling architecture.

The new software agent may determine that an individual prior component contains useful logic or requirements.

That does not convert the previous Cloudflare system back into the starting platform.

Nothing should be reused solely because it already exists.

Nothing should be discarded solely because it came from the previous implementation.

The purpose of reviewing previous material is to understand the project and recover anything genuinely useful.

The purpose is not to restart the abandoned Cloudflare build.

Required interpretation of previous Cloudflare language

When reviewing older source material, apply the following rule.

If a statement describes **what the finished system must accomplish**, preserve the requirement.

If a statement describes **Cloudflare as the specific mechanism used to accomplish it**, remove or replace only the Cloudflare-specific mechanism.

Examples:

Old platform-specific statement

Store originals and derivatives in R2.

Preserved requirement

Store originals and derivatives in the appropriate persistent storage containers.

Old platform-specific statement

Execute routing through Cloudflare Workers.

Preserved requirement

Execute the required routing through the production server/runtime.

Old platform-specific statement

Persist state through Durable Objects or D1.

Preserved requirement

Persist the required system and workflow state through the production persistence layer.

Old platform-specific statement

Reconcile existing Cloudflare resources before deployment.

New-build interpretation

Do not treat the previous Cloudflare deployment as the implementation being continued. Build the required production environment on the replacement platform.

The functional requirement survives.

The obsolete platform binding does not.

No-scope-change rule

The receiving agent must not use this platform transition to:

- reinterpret the project's purpose;
- reduce the build;
- redefine the end goal;
- create a smaller MVP as a substitute for the requested system;
- remove MCP;
- remove the live server;

- remove the HTML dashboard;
- remove the LLM layer;
- weaken the guardrails;
- remove storage containers;
- remove automatic file workflows;
- remove automatic photo workflows;
- remove analysis;
- remove appropriate renaming and organization;
- remove automatic routing;
- remove living context;
- remove continuity;
- remove evidence or provenance requirements;
- remove approval/review behavior;
- remove the permanent workforce;
- merge occupational roles;
- replace the workforce with generic agents;
- turn the system into a developer-only interface;
- require Dayna to manually administer the technical architecture;
- treat the old Cloudflare implementation as controlling.

These would be changes to the project.

They are not authorized by this platform change.

Software-agent implementation authority

The software/build agent is responsible for implementing the already-defined system on the replacement platform.

Where the project specification does not prescribe a specific technical mechanism, the software agent may make the technical implementation decisions necessary to satisfy the requirements.

Those decisions are implementation decisions.

They are not authority to change the requirements themselves.

The controlling distinction is:

Dayna has defined what the system is supposed to become and what it must do.

The software agent determines how to build that defined system on the replacement platform.

Final controlling rule

For avoidance of doubt:

The project has not been replaced.

The system has not been reduced.

The end goal has not been rewritten.

The permanent workforce has not been redesigned.

The required MCP, live HTML dashboard/server, LLM, guardrails, domain hosting, storage containers, automatic file and photo workflows, routing, continuity, and related system functions remain.

Only the previous Cloudflare platform and the assumption that its existing implementation must be continued have been removed.

Same build. Same end goal. Same requirements. New platform. New implementation from scratch.
